1 Transitions

This theory contains more facts about closure, the definition of full transformations, and well-foundedness.

1.1 More theorems about Closures

This is the equivalent of $?r \le ?s \Longrightarrow ?r^{**} \le ?s^{**}$ for *tranclp*

lemma *tranclp-mono-explicit*:
r^{++} a $b \Longrightarrow r \le s \Longrightarrow s^{++}$ a b
using *rtranclp-mono* **by** (*auto dest*!: *tranclpD intro*: *rtranclp-into-tranclp2*)

lemma *tranclp-mono*:
assumes *mono*: $r \le s$
shows $r^{++} \le s^{++}$
using *rtranclp-mono*[*OF mono*] *mono* **by** (*auto dest*!: *tranclpD intro*: *rtranclp-into-tranclp2*)

lemma *tranclp-idemp-rel*:
R^{++++} a $b \longleftrightarrow R^{++}$ a b
apply (*rule iffI*)

```
    prefer 2 apply blast
  by (induction rule: tranclp-induct) auto
```

Equivalent of $?r^{****} = ?r^{**}$

```
lemma trancl-idemp: (r^+)^+ = r^+
  by simp

lemmas tranclp-idemp[simp] = trancl-idemp[to-pred]
```

This theorem already exists as $?r^{**}\ ?a\ ?b \equiv ?a = ?b \vee ?r^{++}\ ?a\ ?b$ (and sledgehammer uses it), but it makes sense to duplicate it, because it is unclear how stable the lemmas in Nitpick are.

```
lemma rtranclp-unfold: rtranclp r a b ⟷ (a = b ∨ tranclp r a b)
  by (meson rtranclp.simps rtranclpD tranclp-into-rtranclp)

lemma tranclp-unfold-end: tranclp r a b ⟷ (∃ a'. rtranclp r a a' ∧ r a' b)
  by (metis rtranclp.rtrancl-refl rtranclp-into-tranclp1 tranclp.cases tranclp-into-rtranclp)

lemma tranclp-unfold-begin: tranclp r a b ⟷ (∃ a'. r a a' ∧ rtranclp r a' b)
  by (meson rtranclp-into-tranclp2 tranclpD)

lemma trancl-set-tranclp: (a, b) ∈ {(b,a). P a b}^+ ⟷ P^++ b a
  apply (rule iffI)
    apply (induction rule: trancl-induct; simp)
  apply (induction rule: tranclp-induct; auto simp: trancl-into-trancl2)
  done

lemma tranclp-rtranclp-rtranclp-rel: R^++** a b ⟷ R^** a b
  by (simp add: rtranclp-unfold)

lemma tranclp-rtranclp-rtranclp[simp]: R^++** = R^**
  by (fastforce simp: rtranclp-unfold)

lemma rtranclp-exists-last-with-prop:
  assumes R x z
  and R^** z z' and P x z
  shows ∃ y y'. R^** x y ∧ R y y' ∧ P y y' ∧ (λa b. R a b ∧ ¬P a b)^** y' z'
  using assms(2,1,3)

2 Various Lemmas

Close to (⋀n. ∀ m<n. ?P m ⟹ ?P n) ⟹ ?P ?n, but with a separation between zero and non-zero, and case names.

```
thm nat-less-induct
lemma nat-less-induct-case[case-names 0 Suc]:
  assumes
    P 0 and
    ⋀n. (∀ m < Suc n. P m) ⟹ P (Suc n)
  shows P n
  apply (induction rule: nat-less-induct)
  by (rename-tac n, case-tac n) (auto intro: assms)
```

This is only proved in simple cases by auto. In assumptions, nothing happens, and *?P (if ?Q then ?x else ?y) = (¬ (?Q ∧ ¬ ?P ?x ∨ ¬ ?Q ∧ ¬ ?P ?y))* can blow up goals (because of other if expression).

```
lemma if-0-1-ge-0[simp]:
  0 < (if P then a else (0::nat)) ⟷ P ∧ 0 < a
  by auto
```

Bounded function have not been defined in Isabelle.

```
definition bounded where
bounded f ⟷ (∃ b. ∀ n. f n ≤ b)

abbreviation unbounded :: ('a ⇒ 'b::ord) ⇒ bool where
unbounded f ≡ ¬ bounded f

lemma not-bounded-nat-exists-larger:
  fixes f :: nat ⇒ nat
  assumes unbound: unbounded f
  shows ∃ n. f n > m ∧ n > n0

   using mult-le-mono2 apply blast
  by (meson assms le-less-trans less-or-eq-imp-le nat-mult-less-cancel-disj split-div-lemma)
```

This lemma is not used, but here to show that a property that can be expected from *bounded* holds.

```
lemma bounded-finite-linorder:
  fixes f :: 'a ⇒ 'a ::{finite, linorder}
  shows bounded f
proof −
  have ⋀x. f x ≤ Max {f x|x. True}
    by (metis (mono-tags) Max-ge finite mem-Collect-eq)
  then show ?thesis
    unfolding bounded-def by blast
qed
```

3 More List

3.1 *upt*

The simplification rules are not very handy, because [*?i..<Suc ?j*] = (*if ?i* ≤ *?j then* [*?i..<?j*] @ [*?j*] *else* []) leads to a case distinction, that we do not want if the condition is not in the context.

```
lemma upt-Suc-le-append: ¬i ≤ j ⟹ [i..<Suc j] = []
  by auto
```

lemmas *upt-simps*[*simp*] = *upt-Suc-append upt-Suc-le-append*

declare *upt.simps*(*2*)[*simp del*]

lemma
  assumes $i \leq n - m$
  shows *take i* $[m..<n] = [m..<m+i]$
  by (*metis Nat.le-diff-conv2 add.commute assms diff-is-0-eq′ linear take-upt upt-conv-Nil*)

The counterpart for this lemma when $n - m < i$ is *length ?xs* $\leq$ *?n* $\Longrightarrow$ *take ?n ?xs* = *?xs*. It is close to $?i + ?m \leq ?n \Longrightarrow$ *take ?m* $[?i..<?n] = [?i..<?i + ?m]$, but seems more general.

lemma *take-upt-bound-minus*[*simp*]:
  assumes $i \leq n - m$
  shows *take i* $[m..<n] = [m\ ..<m+i]$
  using *assms* **by** (*induction i*) *auto*

lemma *append-cons-eq-upt*:
  assumes A @ $B = [m..<n]$
  shows $A = [m\ ..<m+$*length* $A]$ **and** $B = [m +$ *length* $A..<n]$
proof −
  have *take* (*length A*) (A @ B) = A **by** *auto*
  moreover
    have *length* $A \leq n - m$ **using** *assms linear calculation* **by** *fastforce*
    then have *take* (*length A*) $[m..<n] = [m\ ..<m+$*length* $A]$ **by** *auto*
  ultimately show $A = [m\ ..<m+$*length* $A]$ **using** *assms* **by** *auto*
  show $B = [m +$ *length* $A..<n]$ **using** *assms* **by** (*metis append-eq-conv-conj drop-upt*)
qed

lemma *length-list-Suc-0*:
  length W = *Suc 0* $\longleftrightarrow$ ($\exists L.\ W = [L]$)
  apply (*cases W*)
    apply *simp*
  apply (*rename-tac a W′*, *case-tac W′*)
  apply *auto*
  done

  then have [m..<n]! (length A) = m + length A by simp
  ultimately have i = m + length A using assms by auto
  then show ?thesis using ⟨B = [Suc m + length A..<n]⟩ by auto
qed

lemma Max-n-upt: Max (insert 0 {Suc 0..<n}) = n − Suc 0
proof (induct n)
  case 0
  then show ?case by simp
next
  case (Suc n) note IH = this
  have i: insert 0 {Suc 0..<Suc n} = insert 0 {Suc 0..< n} ∪ {n} by auto
  show ?case using IH unfolding i by auto
```

```
qed
```

```
lemma upt-decomp-lt:
  assumes H: xs @ i # ys @ j # zs = [m ..< n]
  shows i < j
proof –
  have xs: xs = [m ..< i] and ys: ys = [Suc i ..< j] and zs: zs = [Suc j ..< n]
    using H by (auto dest: append-cons-eq-upt-length-i append-cons-eq-upt-length-i-end)
  show ?thesis
    by (metis append-cons-eq-upt-length-i-end assms lessI less-trans self-append-conv2
      upt-eq-Cons-conv upt-rec ys)
qed
```

3.2 Lexicographic Ordering

```
lemma lexn-Suc:
  (x # xs, y # ys) ∈ lexn r (Suc n) ⟷
  (length xs = n ∧ length ys = n) ∧ ((x, y) ∈ r ∨ (x = y ∧ (xs, ys) ∈ lexn r n))
  by (auto simp: map-prod-def image-iff lex-prod-def)
```

```
lemma lexn-n:
  n > 0 ⟹ (x # xs, y # ys) ∈ lexn r n ⟷
  (length xs = n−1 ∧ length ys = n−1) ∧ ((x, y) ∈ r ∨ (x = y ∧ (xs, ys) ∈ lexn r (n − 1)))
  apply (cases n)
   apply simp
  by (auto simp: map-prod-def image-iff lex-prod-def)
```

There is some subtle point in the proof here. *1* is converted to *Suc 0*, but *2* is not: meaning that *1* is automatically simplified by default using the default simplification rule *lexn ?r 0* = {}
lexn ?r (*Suc ?n*) = *map-prod* (λ(*x*, *xs*). *x* # *xs*) (λ(*x*, *xs*). *x* # *xs*) ‘ (*?r* <∗*lex*∗> *lexn ?r ?n*) ∩ {(*xs*, *ys*). *length xs* = *Suc ?n* ∧ *length ys* = *Suc ?n*}. However, the latter needs additional simplification rule.

```
lemma lexn2-conv:
  ([a, b], [c, d]) ∈ lexn r 2 ⟷ (a, c) ∈ r ∨ (a = c ∧ (b, d) ∈r)
  by (auto simp: lexn-n simp del: lexn.simps(2))
```

```
lemma lexn3-conv:
  ([a, b, c], [a′, b′, c′]) ∈ lexn r 3 ⟷
    (a, a′) ∈ r ∨ (a = a′ ∧ (b, b′) ∈ r) ∨ (a = a′ ∧ b = b′ ∧ (c, c′) ∈ r)
  by (auto simp: lexn-n simp del: lexn.simps(2))
```

3.3 Remove

3.3.1 More lemmas about remove

```
lemma remove1-nil:
  remove1 (− L) W = [] ⟷ (W = [] ∨ W = [−L])
  by (cases W) auto
```

```
lemma remove1-mset-single-add:
  a ≠ b ⟹ remove1-mset a ({#b#} + C) = {#b#} + remove1-mset a C
  remove1-mset a ({#a#} + C) = C
  by (auto simp: multiset-eq-iff)
```

3.3.2 Remove under condition

This function removes the first element when the condition *f* holds. It generalises *remove1*.

```
fun remove1-cond where
remove1-cond f [] = [] |
remove1-cond f (C' # L) = (if f  C' then L else C' # remove1-cond f L)

lemma remove1 x xs = remove1-cond ((op =) x) xs
  by (induction xs) auto

lemma mset-map-mset-remove1-cond:
  mset (map mset (remove1-cond (λL. mset L = mset a) C)) =
    remove1-mset (mset a) (mset (map mset C))
  by (induction C) (auto simp: ac-simps remove1-mset-single-add)
```

We can also generalise *removeAll*, which is close to *filter*:

```
fun removeAll-cond where
removeAll-cond f [] = [] |
removeAll-cond f (C' # L) =
  (if f C' then removeAll-cond f L else C' # removeAll-cond f L)

lemma removeAll x xs = removeAll-cond ((op =) x) xs
  by (induction xs) auto

lemma removeAll-cond P xs = filter (λx. ¬P x) xs
  by (induction xs) auto

lemma mset-map-mset-removeAll-cond:
  mset (map mset (removeAll-cond (λb. mset b = mset a) C))
    = removeAll-mset (mset a) (mset (map mset C))
  by (induction C) (auto simp: ac-simps mset-less-eqI multiset-diff-union-assoc)
```

Take from `../lib/Multiset_More.thy`, but named:

```
abbreviation union-mset-list where
union-mset-list xs ys ≡ case-prod append (fold (λx (ys, zs). (remove1 x ys, x # zs)) xs (ys, []))

lemma union-mset-list:
  mset xs #∪ mset ys = mset (union-mset-list xs ys)
proof −
  have ⋀zs. mset (case-prod append (fold (λx (ys, zs). (remove1 x ys, x # zs)) xs (ys, zs))) =
      (mset xs #∪ mset ys) + mset zs
    by (induct xs arbitrary: ys) (simp-all add: multiset-eq-iff)
  then show ?thesis by simp
qed

4 Logics

In this section we define the syntax of the formula and an abstraction over it to have simpler proofs. After that we define some properties like subformula and rewriting.

4.1 Definition and abstraction

The propositional logic is defined inductively. The type parameter is the type of the variables.

```
datatype 'v propo =
  FT | FF | FVar 'v | FNot 'v propo | FAnd  'v propo  'v propo | FOr  'v propo  'v propo
  | FImp  'v propo  'v propo | FEq  'v propo  'v propo
```

We do not define any notation for the formula, to distinguish properly between the formulas and Isabelle's logic.

To ease the proofs, we will write the the formula on a homogeneous manner, namely a connecting argument and a list of arguments.

```
datatype 'v connective = CT | CF | CVar 'v | CNot | CAnd | COr | CImp | CEq
```

```
abbreviation nullary-connective ≡ {CF} ∪ {CT} ∪ {CVar x | x. True}
definition binary-connectives ≡ {CAnd, COr, CImp, CEq}
```

We define our own induction principal: instead of distinguishing every constructor, we group them by arity.

```
lemma propo-induct-arity[case-names nullary unary binary]:
  fixes φ ψ :: 'v propo
  assumes nullary: (⋀φ x. φ = FF ∨ φ = FT ∨ φ = FVar x ⟹ P φ)
  and unary: (⋀ψ. P ψ ⟹ P (FNot ψ))
  and binary: (⋀φ ψ1 ψ2. P ψ1 ⟹ P ψ2 ⟹ φ = FAnd ψ1 ψ2 ∨ φ = FOr ψ1 ψ2 ∨ φ = FImp
ψ1 ψ2
    ∨ φ = FEq ψ1 ψ2 ⟹ P φ)
  shows P ψ
  apply (induct rule: propo.induct)
  using assms by metis+
```

The function *conn* is the interpretation of our representation (connective and list of arguments). We define any thing that has no sense to be false

```
fun conn :: 'v connective ⇒ 'v propo list ⇒ 'v propo where
conn CT [] = FT |
conn CF [] = FF |
conn (CVar v) [] = FVar v |
conn CNot [φ] = FNot φ |
conn CAnd (φ # [ψ]) = FAnd φ ψ |
conn COr (φ # [ψ]) = FOr φ ψ |
conn CImp (φ # [ψ]) = FImp φ ψ |
conn CEq (φ # [ψ]) = FEq φ ψ |
conn - - = FF
```

We will often use case distinction, based on the arity of the *'v connective*, thus we define our own splitting principle.

```
lemma connective-cases-arity[case-names nullary binary unary]:
  assumes nullary: ⋀x. c = CT ∨ c = CF ∨ c = CVar x ⟹ P
  and binary: c ∈ binary-connectives ⟹ P
  and unary: c = CNot  ⟹ P
  shows P
  using assms by (cases c) (auto simp: binary-connectives-def)

lemma connective-cases-arity-2[case-names nullary unary binary]:
  assumes nullary: c ∈ nullary-connective ⟹ P
  and unary: c = CNot  ⟹ P
  and binary: c ∈ binary-connectives ⟹ P
  shows P
  using assms by (cases c, auto simp add: binary-connectives-def)
```

Our previous definition is not necessary correct (connective and list of arguments) , so we define an inductive predicate.

```
inductive wf-conn :: 'v connective ⇒ 'v propo list ⇒ bool for c :: 'v connective where
wf-conn-nullary[simp]: (c = CT ∨ c = CF ∨ c  = CVar v) ⟹ wf-conn c [] |
wf-conn-unary[simp]: c = CNot ⟹ wf-conn c [ψ] |
wf-conn-binary[simp]: c ∈ binary-connectives ⟹ wf-conn c (ψ # ψ' # [])
thm wf-conn.induct
lemma wf-conn-induct[consumes 1, case-names CT CF CVar CNot COr CAnd CImp CEq]:
  assumes wf-conn c x and
    (⋀v. c = CT ⟹ P []) and
    (⋀v. c = CF ⟹ P []) and
    (⋀v. c = CVar v ⟹ P []) and
    (⋀ψ. c = CNot ⟹ P [ψ]) and
    (⋀ψ ψ'. c = COr ⟹ P [ψ, ψ'])  and
    (⋀ψ ψ'. c = CAnd ⟹ P [ψ, ψ'])  and
    (⋀ψ ψ'. c = CImp ⟹ P [ψ, ψ'])  and
    (⋀ψ ψ'. c = CEq ⟹ P [ψ, ψ'])
  shows  P x
  using assms by induction (auto simp: binary-connectives-def)
```

4.2 properties of the abstraction

First we can define simplification rules.

```
lemma wf-conn-conn[simp]:
  wf-conn CT l ⟹ conn CT l = FT
  wf-conn CF l ⟹ conn CF l = FF
  wf-conn (CVar x) l ⟹ conn (CVar x) l = FVar x
  apply (simp-all add: wf-conn.simps)
  unfolding binary-connectives-def by simp-all

lemma wf-conn-list-decomp[simp]:
  wf-conn CT l ⟷ l = []
  wf-conn CF l ⟷ l = []
  wf-conn (CVar x) l ⟷ l = []
  wf-conn CNot (ξ @ φ # ξ') ⟷ ξ = [] ∧ ξ' = []
  apply (simp-all add: wf-conn.simps)
       unfolding binary-connectives-def apply simp-all
  by (metis append-Nil append-is-Nil-conv list.distinct(1) list.sel(3) tl-append2)

lemma wf-conn-list:
  wf-conn c l ⟹ conn c l = FT ⟷ (c = CT ∧ l = [])
  wf-conn c l ⟹ conn c l = FF ⟷ (c = CF ∧ l = [])
  wf-conn c l ⟹ conn c l = FVar x ⟷ (c = CVar x ∧ l = [])
  wf-conn c l ⟹ conn c l = FAnd a b ⟷ (c = CAnd ∧ l = a # b # [])
  wf-conn c l ⟹ conn c l = FOr a b ⟷ (c = COr ∧ l = a # b # [])
  wf-conn c l ⟹ conn c l = FEq a b ⟷ (c = CEq ∧ l = a # b # [])
  wf-conn c l ⟹ conn c l = FImp a b ⟷ (c = CImp ∧ l = a # b # [])
  wf-conn c l ⟹ conn c l = FNot a ⟷ (c = CNot ∧ l = a # [])
  apply (induct l rule: wf-conn.induct)
  unfolding binary-connectives-def by auto
```

In the binary connective cases, we will often decompose the list of arguments (of length 2) into two elements.

```
lemma list-length2-decomp: length l = 2 ⟹ (∃ a b. l = a # b # [])
  apply (induct l, auto)
  by (rename-tac l, case-tac l, auto)
```

wf-conn for binary operators means that there are two arguments.

```
lemma wf-conn-bin-list-length:
  fixes l :: 'v propo list
  assumes conn: c ∈ binary-connectives
  shows length l = 2 ⟷ wf-conn c l
proof
  assume length l = 2
  then show wf-conn c l using wf-conn-binary list-length2-decomp using conn by metis
next
  assume wf-conn c l
  then show length l = 2 (is ?P l)
    proof (cases rule: wf-conn.induct)
      case wf-conn-nullary
      then show ?P [] using conn binary-connectives-def
        using connective.distinct(11) connective.distinct(13) connective.distinct(9) by blast
    next
      fix ψ :: 'v propo
      case wf-conn-unary
      then show ?P [ψ] using conn binary-connectives-def
        using connective.distinct  by blast
    next
      fix ψ ψ':: 'v propo
      show ?P [ψ, ψ'] by auto
    qed
qed

lemma wf-conn-not-list-length[iff]:
  fixes l :: 'v propo list
  shows wf-conn CNot l ⟷ length l = 1
  apply auto
  apply (metis append-Nil connective.distinct(5,17,27) length-Cons list.size(3) wf-conn.simps
    wf-conn-list-decomp(4))
  by (simp add: length-Suc-conv wf-conn.simps)
```

Decomposing the Not into an element is moreover very useful.

```
lemma wf-conn-Not-decomp:
  fixes l :: 'v propo list and a :: 'v
  assumes corr: wf-conn CNot l
  shows ∃ a. l = [a]
  by (metis (no-types, lifting) One-nat-def Suc-length-conv corr length-0-conv
    wf-conn-not-list-length)
```

The *wf-conn* remains correct if the length of list does not change. This lemma is very useful when we do one rewriting step

```
lemma wf-conn-no-arity-change:
  length l = length l' ⟹ wf-conn c l ⟷ wf-conn c l'
proof –
  {
    fix l l'
    have length l = length l' ⟹ wf-conn c l ⟹ wf-conn c l'
      apply (cases c l rule: wf-conn.induct, auto)
      by (metis wf-conn-bin-list-length)
  }
  then show length l = length l' ⟹ wf-conn c l = wf-conn c l' by metis
qed

lemma wf-conn-no-arity-change-helper:
  length (ξ @ φ # ξ') = length (ξ @ φ' # ξ')
  by auto
```

The injectivity of *conn* is useful to prove equality of the connectives and the lists.

```
lemma conn-inj-not:
  assumes correct: wf-conn c l
  and conn: conn c l = FNot ψ
  shows c = CNot and l = [ψ]
  apply (cases c l rule: wf-conn.cases)
  using correct conn unfolding binary-connectives-def apply auto
  apply (cases c l rule: wf-conn.cases)
  using correct conn unfolding binary-connectives-def by auto

lemma conn-inj:
  fixes c ca :: 'v connective and l ψs :: 'v propo list
  assumes corr: wf-conn ca l
  and corr': wf-conn c ψs
  and eq: conn ca l = conn c ψs
  shows ca = c ∧ ψs = l
  using corr
proof (cases ca l rule: wf-conn.cases)
  case (wf-conn-nullary v)
  then show ca = c ∧ ψs = l using assms
      by (metis conn.simps(1) conn.simps(2) conn.simps(3) wf-conn-list(1–3))
next
  case (wf-conn-unary ψ')
  then have *: FNot ψ' = conn c ψs using conn-inj-not eq assms by auto
  then have c = ca by (metis conn-inj-not(1) corr' wf-conn-unary(2))
  moreover have ψs = l using * conn-inj-not(2) corr' wf-conn-unary(1) by force
  ultimately show ca = c ∧ ψs = l by auto
next
  case (wf-conn-binary ψ' ψ'')
  then show ca = c ∧ ψs = l
    using eq corr' unfolding binary-connectives-def apply (cases ca, auto simp add: wf-conn-list)
    using wf-conn-list(4–7) corr' by metis+
qed
```

4.3 Subformulas and properties

A characterization using sub-formulas is interesting for rewriting: we will define our relation on the sub-term level, and then lift the rewriting on the term-level. So the rewriting takes place on a subformula.

```
inductive subformula :: 'v propo ⇒ 'v propo ⇒ bool  (infix ≼ 45) for φ where
subformula-refl[simp]: φ ≼ φ |
subformula-into-subformula: ψ ∈ set l ⟹ wf-conn c l ⟹ φ ≼ ψ ⟹ φ ≼ conn c l
```

On the *subformula-into-subformula*, we can see why we use our *conn* representation: one case is enough to express the subformulas property instead of listing all the cases.

This is an example of a property related to subformulas.

```
lemma subformula-in-subformula-not:
shows b: FNot φ ≼ ψ ⟹ φ ≼ ψ
  apply (induct rule: subformula.induct)
  using subformula-into-subformula wf-conn-unary subformula-refl  list.set-intros(1) subformula-refl
    by (fastforce intro: subformula-into-subformula)+

5 Semantics over the syntax

Given the syntax defined above, we define a semantics, by defining an evaluation function *eval*. This function is the bridge between the logic as we define it here and the built-in logic of Isabelle.

```
fun eval :: ('v ⇒ bool) ⇒ 'v propo ⇒ bool (infix ⊨ 50) where
𝒜 ⊨ FT = True |
𝒜 ⊨ FF = False |
𝒜 ⊨ FVar v = (𝒜 v) |
𝒜 ⊨ FNot φ = (¬(𝒜⊨ φ)) |
𝒜 ⊨ FAnd φ1 φ2 = (𝒜⊨φ1 ∧ 𝒜⊨φ2) |
𝒜 ⊨ FOr φ1 φ2 = (𝒜⊨φ1 ∨ 𝒜⊨φ2) |
𝒜 ⊨ FImp φ1 φ2 = (𝒜⊨φ1 ⟶ 𝒜⊨φ2)  |
𝒜 ⊨ FEq φ1 φ2 = (𝒜⊨φ1 ⟷ 𝒜 ⊨φ2)

definition evalf (infix ⊨f 50) where
evalf φ ψ = (∀ A. A ⊨ φ ⟶ A ⊨ ψ)
```

The deduction rule is in the book. And the proof looks like to the one of the book.

```
theorem deduction-theorem:
  (φ ⊨f ψ) ⟷ (∀ A. (A ⊨ FImp φ ψ))
proof
  assume H: φ ⊨f ψ
  {
    fix A
    have A ⊨ FImp φ ψ
      proof (cases A ⊨ φ)
        case True
        then have A ⊨ ψ using H unfolding evalf-def by metis
        then show A ⊨ FImp φ ψ by auto
      next
        case False
        then show A ⊨ FImp φ ψ by auto
      qed
  }
  then show ∀ A. A ⊨ FImp φ ψ by blast
next
  assume A: ∀ A. A ⊨ FImp φ ψ
  show φ ⊨f ψ
    proof (rule ccontr)
      assume ¬ φ ⊨f ψ
      then obtain A where A ⊨ φ and ¬ A ⊨ ψ using evalf-def by metis
      then have ¬ A ⊨ FImp φ ψ by auto
      then show False using A by blast
    qed
qed
```

A shorter proof:

```
lemma φ ⊨f ψ ⟷ (∀ A. A⊨ FImp φ ψ)
  by (simp add: evalf-def)

definition same-over-set:: ('v ⇒ bool) ⇒('v ⇒ bool) ⇒ 'v set ⇒ bool where
same-over-set A B S = (∀ c∈S. A c = B c)
```

If two mapping *A* and *B* have the same value over the variables, then the same formula are satisfiable.

```
lemma same-over-set-eval:
  assumes same-over-set A B (vars-of-prop φ)
  shows A ⊨ φ ⟷ B ⊨ φ
  using assms unfolding same-over-set-def by (induct φ, auto)

end
theory Prop-Abstract-Transformation
imports Main Prop-Logic Wellfounded-More

begin
```

This file is devoted to abstract properties of the transformations, like consistency preservation and lifting from terms to proposition.

6 Rewrite systems and properties

6.1 Lifting of rewrite rules

We can lift a rewrite relation r over a full1 formula: the relation *r* works on terms, while *propo-rew-step* works on formulas.

```
inductive propo-rew-step :: ('v propo ⇒ 'v propo ⇒ bool) ⇒ 'v propo ⇒ 'v propo ⇒ bool
  for r :: 'v propo ⇒ 'v propo ⇒ bool where
global-rel: r φ ψ ⟹ propo-rew-step r φ ψ |
propo-rew-one-step-lift: propo-rew-step r φ φ' ⟹ wf-conn c (ψs @ φ # ψs')
  ⟹ propo-rew-step r (conn c (ψs @ φ # ψs')) (conn c (ψs @ φ'# ψs'))
```

Here is a more precise link between the lifting and the subformulas: if a rewriting takes place between φ and φ', then there are two subformulas ψ in φ and ψ' in φ', ψ' is the result of the rewriting of r on ψ.

This lemma is only a health condition:

```
lemma propo-rew-step-subformula-imp:
shows propo-rew-step r φ φ' ⟹ ∃ ψ ψ'. ψ ≼ φ ∧ ψ' ≼ φ' ∧ r ψ ψ'
  apply (induct rule: propo-rew-step.induct)
    using subformula.simps subformula-into-subformula apply blast
  using wf-conn-no-arity-change subformula-into-subformula wf-conn-no-arity-change-helper
  in-set-conv-decomp by metis
```

The converse is moreover true: if there is a ψ and ψ', then every formula φ containing ψ, can be rewritten into a formula φ', such that it contains φ'.

```
lemma propo-rew-step-subformula-rec:
  fixes ψ ψ' φ :: 'v propo
  shows ψ ≼ φ ⟹ r ψ ψ' ⟹ (∃φ'. ψ' ≼ φ' ∧ propo-rew-step r φ φ')
proof (induct φ rule: subformula.induct)

  by (simp add: star-consistency-preservation-explicit preserves-un-sat-def)
```

6.3 Full Lifting

In the previous a relation was lifted to a formula, now we define the relation such it is applied as long as possible. The definition is thus simply: it can be derived and nothing more can be derived.

```
lemma full-ropo-rew-step-preservers-val[simp]:
preserves-un-sat r ⟹ preserves-un-sat (full (propo-rew-step r))
  by (metis full-def preserves-un-sat-def star-consistency-preservation)
```

```
lemma full-propo-rew-step-subformula:
full (propo-rew-step r) φ' φ ⟹ ¬(∃ ψ ψ'. ψ ≼ φ ∧ r ψ ψ')
```

```
  unfolding full-def using propo-rew-step-subformula-rec by metis
```

7 Transformation testing

7.1 Definition and first properties

To prove correctness of our transformation, we create a *all-subformula-st* predicate. It tests recursively all subformulas. At each step, the actual formula is tested. The aim of this *test-symb* function is to test locally some properties of the formulas (i.e. at the level of the connective or at first level). This allows a clause description between the rewrite relation and the *test-symb*

```
definition all-subformula-st :: ('a propo ⇒ bool) ⇒ 'a propo ⇒ bool  where
all-subformula-st test-symb φ ≡ ∀ψ. ψ ≼ φ ⟶ test-symb ψ

lemma test-symb-imp-all-subformula-st[simp]:
  test-symb FT ⟹ all-subformula-st test-symb FT
  test-symb FF ⟹ all-subformula-st test-symb FF
  test-symb (FVar  x) ⟹ all-subformula-st test-symb (FVar x)
  unfolding all-subformula-st-def using  subformula-leaf by metis+

lemma all-subformula-st-test-symb-true-phi:
  all-subformula-st test-symb φ ⟹ test-symb φ
  unfolding all-subformula-st-def by auto

lemma all-subformula-st-decomp-imp:
  wf-conn c l ⟹ (test-symb (conn c l) ∧ (∀φ∈ set l. all-subformula-st test-symb φ))
  ⟹ all-subformula-st test-symb (conn c l)
  unfolding all-subformula-st-def by auto
```

To ease the finding of proofs, we give some explicit theorem about the decomposition.

```
lemma all-subformula-st-decomp-rec:
  all-subformula-st test-symb  (conn c l) ⟹ wf-conn c l
    ⟹ (test-symb (conn c l) ∧ (∀φ∈ set l. all-subformula-st test-symb φ))
  unfolding all-subformula-st-def by auto

7.2 Invariant conservation

If two rewrite relation are independant (or at least independant enough), then the property characterizing the first relation *all-subformula-st test-symb* remains true. The next show the same property, with changes in the assumptions.

The assumption $\forall \varphi'\, \psi.\ \varphi' \preceq \Phi \longrightarrow r\ \varphi'\ \psi \longrightarrow$ *all-subformula-st test-symb* $\varphi' \longrightarrow$ *all-subformula-st test-symb* ψ means that rewriting with r does not mess up the property we want to preserve locally.

The previous assumption is not enough to go from r to *propo-rew-step* r: we have to add the assumption that rewriting inside does not mess up the term: $\forall c\ \xi\ \varphi\ \xi'\ \varphi'.\ \varphi \preceq \Phi \longrightarrow$ *propo-rew-step* $r\ \varphi\ \varphi' \longrightarrow$ *wf-conn* $c\ (\xi\ @\ \varphi\ \#\ \xi') \longrightarrow$ *test-symb* (*conn* $c\ (\xi\ @\ \varphi\ \#\ \xi')) \longrightarrow$ *test-symb* $\varphi' \longrightarrow$ *test-symb* (*conn* $c\ (\xi\ @\ \varphi'\ \#\ \xi'))$

7.2.1 Invariant while lifting of the rewriting relation

The condition $\varphi \preceq \Phi$ (that will by used with $\Phi = \varphi$ most of the time) is here to ensure that the recursive conditions on Φ will moreover hold for the subterm we are rewriting. For example if there is no equivalence symbol in Φ, we do not have to care about equivalence symbols in the two previous assumptions.

```

```

Given the previous definition about abstract rewriting and theorem about them, we now have the detailed rule making the transformation into CNF/DNF.

8 Rewrite Rules

The idea of Christoph Weidenbach's book is to remove gradually the operators: first equivalencies, then implication, after that the unused true/false and finally the reorganizing the or/and. We will prove each transformation seperately.

8.1 Elimination of the equivalences

The first transformation consists in removing every equivalence symbol.

```
inductive elim-equiv :: 'v propo ⇒ 'v propo ⇒ bool where
elim-equiv[simp]: elim-equiv (FEq φ ψ) (FAnd (FImp φ ψ)  (FImp ψ φ))

lemma elim-equiv-transformation-consistent:
A ⊨ FEq φ ψ ⟷ A ⊨ FAnd (FImp φ ψ) (FImp ψ φ)
  by auto

lemma elim-equiv-explicit: elim-equiv φ ψ ⟹ ∀ A. A ⊨ φ ⟷ A ⊨ ψ
  by (induct rule: elim-equiv.induct, auto)

lemma elim-equiv-consistent: preserves-un-sat elim-equiv
  unfolding preserves-un-sat-def by (simp add: elim-equiv-explicit)

lemma elimEquv-lifted-consistant:
  preserves-un-sat (full (propo-rew-step elim-equiv))
  by (simp add: elim-equiv-consistent)
```

This function ensures that there is no equivalencies left in the formula tested by *no-equiv-symb*.

```
fun no-equiv-symb :: 'v propo ⇒ bool where
no-equiv-symb (FEq - -) = False |
no-equiv-symb - = True
```

Given the definition of *no-equiv-symb*, it does not depend on the formula, but only on the connective used.

```
lemma no-equiv-symb-conn-characterization[simp]:
  fixes c :: 'v connective and l :: 'v propo list
  assumes wf: wf-conn c l
  shows no-equiv-symb (conn c l) ⟷ c ≠ CEq
    by (metis connective.distinct(13,25,35,43) wf no-equiv-symb.elims(3) no-equiv-symb.simps(1)
      wf-conn.cases wf-conn-list(6))

definition no-equiv where no-equiv = all-subformula-st no-equiv-symb

lemma no-equiv-eq[simp]:
  fixes φ ψ :: 'v propo
  shows
```

```
    ¬no-equiv (FEq φ ψ)
    no-equiv FT
    no-equiv FF
  using no-equiv-symb.simps(1) all-subformula-st-test-symb-true-phi unfolding no-equiv-def by auto
```

The following lemma helps to reconstruct *no-equiv* expressions: this representation is easier to use than the set definition.

```
lemma all-subformula-st-decomp-explicit-no-equiv[iff]:
fixes φ ψ :: 'v propo
shows
  no-equiv (FNot φ) ⟷ no-equiv φ
  no-equiv (FAnd φ ψ) ⟷ (no-equiv φ ∧ no-equiv ψ)
  no-equiv (FOr φ ψ) ⟷ (no-equiv φ ∧ no-equiv ψ)
  no-equiv (FImp φ ψ) ⟷ (no-equiv φ ∧ no-equiv ψ)
  by (auto simp: no-equiv-def)
```

A theorem to show the link between the rewrite relation *elim-equiv* and the function *no-equiv-symb*. This theorem is one of the assumption we need to characterize the transformation.

```
lemma no-equiv-elim-equiv-step:
  fixes φ :: 'v propo
  assumes no-equiv: ¬ no-equiv φ

10 More aggressive simplifications: Removing true and false at the beginning

10.1 Transformation

We should remove *FT* and *FF* at the beginning and not in the middle of the algorithm. To do this, we have to use more rules (one for each connective):

inductive *elimTBFull* **where**
ElimTBFull1 [*simp*]: *elimTBFull* (*FAnd* φ *FT*) φ |
ElimTBFull1′ [*simp*]: *elimTBFull* (*FAnd FT* φ) φ |

ElimTBFull2 [*simp*]: *elimTBFull* (*FAnd* φ *FF*) *FF* |
ElimTBFull2′ [*simp*]: *elimTBFull* (*FAnd FF* φ) *FF* |

ElimTBFull3 [*simp*]: *elimTBFull* (*FOr* φ *FT*) *FT* |
ElimTBFull3′ [*simp*]: *elimTBFull* (*FOr FT* φ) *FT* |

ElimTBFull4 [*simp*]: *elimTBFull* (*FOr* φ *FF*) φ |
ElimTBFull4′ [*simp*]: *elimTBFull* (*FOr FF* φ) φ |

ElimTBFull5 [*simp*]: *elimTBFull* (*FNot FT*) *FF* |
ElimTBFull5′ [*simp*]: *elimTBFull* (*FNot FF*) *FT* |

```
ElimTBFull6-l[simp]: elimTBFull (FImp FT φ) φ |
ElimTBFull6-l'[simp]: elimTBFull (FImp FF φ) FT |
ElimTBFull6-r[simp]: elimTBFull (FImp φ FT) FT |
ElimTBFull6-r'[simp]: elimTBFull (FImp φ FF) (FNot φ) |

ElimTBFull7-l[simp]: elimTBFull (FEq FT φ) φ |
ElimTBFull7-l'[simp]: elimTBFull (FEq FF φ) (FNot φ) |
ElimTBFull7-r[simp]: elimTBFull (FEq φ FT) φ |
ElimTBFull7-r'[simp]: elimTBFull (FEq φ FF) (FNot φ)
```

The transformation is still consistent.

```
lemma elimTBFull-consistent: preserves-un-sat elimTBFull
proof –
  {
    fix φ ψ:: 'b propo
    have elimTBFull φ ψ ⟹ ∀ A. A ⊨ φ ⟷ A ⊨ ψ
      by (induct-tac rule: elimTBFull.inducts, auto)
  }
  then show ?thesis using preserves-un-sat-def by auto
qed
```

Contrary to the theorem ⟦*no-equiv ?φ*; *no-imp ?φ*; *?ψ* $\preceq$ *?φ*; $\neg$ *no-T-F-symb-except-toplevel ?ψ*⟧ $\Longrightarrow \exists \psi'$. *elimTB ?ψ ψ'*, we do not need the assumption *no-equiv φ* and *no-imp φ*, since our transformation is more general.

```
lemma no-T-F-symb-except-toplevel-step-exists':
  fixes φ :: 'v propo
  shows ψ ≼ φ ⟹ ¬ no-T-F-symb-except-toplevel ψ ⟹ ∃ψ'. elimTBFull ψ ψ'

10.3 The new CNF and DNF transformation

The transformation is the same as before, but the order is not the same.

```
definition dnf-rew' :: 'a propo ⇒ 'a propo ⇒ bool where
dnf-rew' =
  (full (propo-rew-step elimTBFull)) OO
  (full (propo-rew-step elim-equiv)) OO
  (full (propo-rew-step elim-imp)) OO
  (full (propo-rew-step pushNeg)) OO
  (full (propo-rew-step pushConj))

lemma dnf-rew'-consistent: preserves-un-sat dnf-rew'
  by (simp add: dnf-rew'-def elimEquv-lifted-consistant elim-imp-lifted-consistant
    elimTBFull-consistent preserves-un-sat-OO pushConj-consistent pushNeg-lifted-consistant)

theorem cnf-transformation-correction:
    dnf-rew' φ φ' ⟹ is-dnf φ'
  unfolding dnf-rew'-def OO-def
  by (meson and-in-or-only-conjunction-in-disj elimTBFull-full-propo-rew-step elim-equiv-inv'

When a formula is in CNF form, then there is equisatisfiability between the multiset version and the CNF form. Remark that the definition for the entailment are slightly different: *op* ⊨ uses a function assigning *True* or *False*, while *op* ⊨*s* uses a set where being in the list means entailment of a literal.

14 Partial Clausal Logic

We here define marked literals (that will be used in both DPLL and CDCL) and the entailment corresponding to it.

14.1 Marked Literals

14.1.1 Definition

```
datatype ('v, 'lvl, 'mark) marked-lit =
  is-marked: Marked (lit-of: 'v literal) (level-of: 'lvl) |
  is-proped: Propagated (lit-of: 'v literal) (mark-of: 'mark)
```

```
lemma marked-lit-list-induct[case-names nil marked proped]:
  assumes P [] and
  ⋀L l xs. P xs ⟹ P (Marked L l # xs) and
  ⋀L m xs. P xs ⟹ P (Propagated L m # xs)
  shows P xs
  using assms apply (induction xs, simp)
  by (rename-tac a xs, case-tac a) auto
```

```
lemma is-marked-ex-Marked:
  is-marked L ⟹ ∃K lvl. L = Marked K lvl
  by (cases L) auto
```

```
type-synonym ('v, 'l, 'm) marked-lits = ('v, 'l, 'm) marked-lit list
```

```
definition lits-of :: ('a, 'b, 'c) marked-lit set ⇒ 'a literal set where
lits-of Ls = lit-of ` Ls
```

```
abbreviation lits-of-l :: ('a, 'b, 'c) marked-lit list ⇒ 'a literal set where
lits-of-l Ls ≡ lits-of (set Ls)
```

```
lemma lits-of-l-empty[simp]:
  lits-of {} = {}
  unfolding lits-of-def by auto
```

```

unfolding *lits-of-def defined-lit-def*
by (*auto simp*: *rev-image-eqI*) (*rename-tac x*, *case-tac x*, *auto*)+

lemma *consistent-add-undefined-lit-consistent*[*simp*]:
assumes
consistent-interp (*lits-of-l Ls*) **and**

```
  undefined-lit Ls L
  shows consistent-interp (insert L (lits-of-l Ls))
  using assms unfolding consistent-interp-def by (auto simp: Marked-Propagated-in-iff-in-lits-of-l)

lemma decided-empty[simp]:
  ¬defined-lit [] L
  unfolding defined-lit-def by simp
```

14.2 Backtracking

```
fun backtrack-split :: ('v, 'l, 'm) marked-lits
  ⇒ ('v, 'l, 'm) marked-lits × ('v, 'l, 'm) marked-lits where
backtrack-split [] = ([], []) |
backtrack-split (Propagated L P # mlits) = apfst ((op #) (Propagated L P)) (backtrack-split mlits) |
backtrack-split (Marked L l # mlits) = ([], Marked L l # mlits)

lemma backtrack-split-fst-not-marked: a ∈ set (fst (backtrack-split l)) ⟹ ¬is-marked a
  by (induct l rule: marked-lit-list-induct) auto

lemma backtrack-split-snd-hd-marked:
  snd (backtrack-split l) ≠ [] ⟹ is-marked (hd (snd (backtrack-split l)))
  by (induct l rule: marked-lit-list-induct) auto

lemma backtrack-split-list-eq[simp]:
  fst (backtrack-split l) @ (snd (backtrack-split l)) = l
  by (induct l rule: marked-lit-list-induct) auto

lemma backtrack-snd-empty-not-marked:
  backtrack-split M = (M'', []) ⟹ ∀ l∈set M. ¬ is-marked l
  by (metis append-Nil2 backtrack-split-fst-not-marked backtrack-split-list-eq snd-conv)

lemma backtrack-split-some-is-marked-then-snd-has-hd:
  ∃ l∈set M. is-marked l ⟹ ∃ M' L' M''. backtrack-split M = (M'', L' # M')
  by (metis backtrack-snd-empty-not-marked list.exhaust prod.collapse)
```

Another characterisation of the result of *backtrack-split*. This view allows some simpler proofs, since *takeWhile* and *dropWhile* are highly automated:

```
lemma backtrack-split-takeWhile-dropWhile:
  backtrack-split M = (takeWhile (Not o is-marked) M, dropWhile (Not o is-marked) M)
proof (induct M)
  case Nil show ?case by simp
next
  case (Cons L M) then show ?case by (cases L) auto
qed
```

14.3 Decomposition with respect to the marked literals

The pattern *get-all-marked-decomposition* [] = [([], [])] is necessary otherwise, we can call the *hd* function in the other pattern.

```
fun get-all-marked-decomposition :: ('a, 'l, 'm) marked-lits
  ⇒ (('a, 'l, 'm) marked-lits × ('a, 'l, 'm) marked-lits) list where
get-all-marked-decomposition (Marked L l # Ls) =
  (Marked L l # Ls, []) # get-all-marked-decomposition Ls |
get-all-marked-decomposition (Propagated L P# Ls) =
  (apsnd ((op #) (Propagated L P)) (hd (get-all-marked-decomposition Ls)))
```

```
    # tl (get-all-marked-decomposition Ls) |

14.6 Abstract Clause Representation

We will abstract the representation of clause and clauses via two locales. We expect our representation to behave like multiset, but the internal representation can be done using list or whatever other representation.

We assume the following:

- there is an equivalent to adding and removing a literal and to taking the union of clauses.

```
locale raw-cls =
  fixes
    mset-cls:: 'cls ⇒ 'v clause and
    insert-cls :: 'v literal ⇒ 'cls ⇒ 'cls and
    remove-lit :: 'v literal ⇒ 'cls ⇒ 'cls
  assumes
    insert-cls[simp]: mset-cls (insert-cls L C) = mset-cls C + {#L#} and
    remove-lit[simp]: mset-cls (remove-lit L C) = remove1-mset L (mset-cls C)
begin
end

locale raw-ccls-union =
  fixes
    mset-cls:: 'cls ⇒ 'v clause and
    union-cls :: 'cls ⇒ 'cls ⇒ 'cls and
    insert-cls :: 'v literal ⇒ 'cls ⇒ 'cls and
    remove-lit :: 'v literal ⇒ 'cls ⇒ 'cls
  assumes
    insert-ccls[simp]: mset-cls (insert-cls L C) = mset-cls C + {#L#} and
    mset-ccls-union-cls[simp]: mset-cls (union-cls C D) = mset-cls C #∪ mset-cls D and
    remove-clit[simp]: mset-cls (remove-lit L C) = remove1-mset L (mset-cls C)
begin
end
```

Instantiation of the previous locale, in an unnamed context to avoid polluating with simp rules

```
context
begin
  interpretation list-cls: raw-cls mset
    op # remove1
    by unfold-locales (auto simp: union-mset-list ex-mset)

  interpretation cls-cls: raw-cls id
    λL C. C + {#L#} remove1-mset
    by unfold-locales (auto simp: union-mset-list)

  interpretation list-cls: raw-ccls-union mset
    union-mset-list
    op # remove1
    by unfold-locales (auto simp: union-mset-list ex-mset)
  interpretation cls-cls: raw-ccls-union id
    op #∪ λL C. C + {#L#} remove1-mset
    by unfold-locales (auto simp: union-mset-list)
end
```

Over the abstract clauses, we have the following properties:

- We can insert a clause
- We can take the union (used only in proofs for the definition of *clauses*)
- there is an operator indicating whether the abstract clause is contained or not
- if a concrete clause is contained the abstract clauses, then there is an abstract clause

```
locale raw-clss =
  raw-cls mset-cls insert-cls remove-lit

15 Measure

This measure show the termination of the core of CDCL: each step improves the number of literals we know for sure.

This measure can also be seen as the increasing lexicographic order: it is an order on bounded sequences, when each element is bounded. The proof involves a measure like the one defined here (the same?).

$\quad \neg no\text{-}step\ backjump\ S$
begin

We cannot add a like condition $atms\text{-}of\ C' \subseteq atms\text{-}of\text{-}ms\ N$ because to ensure that we can backjump even if the last decision variable has disappeared.

The part of the condition $atm\text{-}of\ L \in atm\text{-}of\ `\ lits\text{-}of\text{-}l\ (F' \mathbin{@} Marked\ K\ ()\ \#\ F)$ is important, otherwise you are not sure that you can backtrack.

16.3.1 Definition

We define dpll with backjumping:

inductive $dpll\text{-}bj :: 'st \Rightarrow 'st \Rightarrow bool$ **for** $S :: 'st$ **where**
$bj\text{-}decide_{NOT}:\ decide_{NOT}\ S\ S' \Longrightarrow dpll\text{-}bj\ S\ S'\ |$
$bj\text{-}propagate_{NOT}:\ propagate_{NOT}\ S\ S' \Longrightarrow dpll\text{-}bj\ S\ S'\ |$
$bj\text{-}backjump:\ backjump\ S\ S' \Longrightarrow dpll\text{-}bj\ S\ S'$

```

Well-foundedness The bounds are the following:

- *1 + card (atms-of-ms A)*: *card (atms-of-ms A)* is an upper bound on the length of the list. As *get-all-marked-decomposition* appends an possibly empty couple at the end, adding one is needed.
- *2 + card (atms-of-ms A)*: *card (atms-of-ms A)* is an upper bound on the number of elements, where adding one is necessary for the same reason as for the bound on the list, and one is needed to have a strict bound.

16.3.4 Normal Forms

We prove that given a normal form of DPLL, with some invariants, the either N is satisfiable and the built valuation M is a model; or N is unsatisfiable.

Idea of the proof: We have to prove tat *satisfiable* N, $\neg$ M $\models$*as* N and there is no remaining step is incompatible.

1. The *decide* rules tells us that every variable in N has a value.
2. $\neg$ M $\models$*as* N tells us that there is conflict.
3. There is at least one decision in the trail (otherwise, M is a model of N).
4. Now if we build the clause with all the decision literals of the trail, we can apply the *backjump* rule.

   The assumption are saying that we have a finite upper bound A for the literals, that we cannot do any step *no-step dpll-bj S*

```

16.7.2 Increasing restarts

To add restarts we needs some assumptions on the predicate (called $cdcl_{NOT}$ here):

- a function f that is strictly monotonic. The first step is actually only used as a restart to clean the state (e.g. to ensure that the trail is empty). Then we assume that $(1::'a) \leq f\ n$ for $(1::'a) \leq n$: it means that between two consecutive restarts, at least one step will be done. This is necessary to avoid sequence. like: full – restart – full – ...

- a measure μ: it should decrease under the assumptions *bound-inv*, whenever a $cdcl_{NOT}$ or a *restart* is done. A parameter is given to μ: for conflict- driven clause learning, it is an upper-bound of the clauses. We are assuming that such a bound can be found after a restart whenever the invariant holds.

- we also assume that the measure decrease after any $cdcl_{NOT}$ step.

- an invariant on the states $cdcl_{NOT}$*-inv* that also holds after restarts.

- it is *not required* that the measure decrease with respect to restarts, but the measure has to be bound by some function μ*-bound* taking the same parameter as μ and the initial state of the considered $cdcl_{NOT}$ chain.

19.3 Invariants

19.3.1 Properties of the trail

We here establish that: * the marks are exactly 1..k where k is the level * the consistency of the trail * the fact that there is no duplicate in the trail.

```

19.3.5 Learned Clause

This invariant shows that:

- the learned clauses are entailed by the initial set of clauses.
- the conflicting clause is entailed by the initial set of clauses.
- the marks are entailed by the clauses. A more precise version would be to show that either these marked are learned or are in the set of clauses

```

19.5.3 Literal of highest level in conflicting clauses

One important property of the *cdcl*$_W$ with strategy is that, whenever a conflict takes place, there is at least a literal of level k involved (except if we have derived the false clause). The reason is that we apply conflicts before a decision is taken.

```

begin
```

20.2 Simple Implementation of DPLL

20.2.1 Combining the propagate and decide: a DPLL step

```
definition DPLL-step :: int dpll_W-marked-lits × int literal list list
  ⇒ int dpll_W-marked-lits × int literal list list where
DPLL-step = (λ(Ms, N).
  (case find-first-unit-clause N Ms of
    Some (L, -) ⇒ (Propagated L () # Ms, N)
  | - ⇒
    if ∃ C ∈ set N. (∀ c ∈ set C. −c ∈ lits-of-l Ms)
    then
      (case backtrack-split Ms of
        (-, L # M) ⇒ (Propagated (− (lit-of L)) () # M, N)
      | (-, -) ⇒ (Ms, N)
      )
    else
    (case find-first-unused-var N (lits-of-l Ms) of
        Some a ⇒ (Marked a () # Ms, N)
      | None ⇒ (Ms, N))))
```

Example of propagation:

```
value DPLL-step ([Marked (Neg 1) ()], [[Pos (1::int), Neg 2]])
```

We define the conversion function between the states as defined in *Prop-DPLL* (with multisets) and here (with lists).

```
abbreviation toS ≡ λ(Ms::(int, unit, unit) marked-lit list)
                    (N:: int literal list list). (Ms, mset (map mset N))
abbreviation toS' ≡ λ(Ms::(int, unit, unit) marked-lit list,
                        N:: int literal list list). (Ms, mset (map mset N))
```

Proof of correctness of *DPLL-step*

```
lemma DPLL-step-is-a-dpll_W-step:
  assumes step: (Ms', N') = DPLL-step (Ms, N)
  and neq: (Ms, N) ≠ (Ms', N')
  shows dpll_W (toS Ms N) (toS Ms' N')

20.2.3 Code export

A conversion to *DPLL-W-Implementation.dpll*$_W$*-state* **definition** *Con* :: (*int*, *unit*, *unit*) *marked-lit list* × *int literal list list*
⇒ *dpll*$_W$*-state* **where**
Con xs = *state-of* (*if dpll*$_W$*-all-inv* (*toS* (*fst xs*) (*snd xs*)) *then xs else* ([], []))
lemma [*code abstype*]:
Con (*rough-state-of S*) = *S*
using *rough-state-of*[*of S*] **unfolding** *Con-def* **by** *auto*

declare *rough-state-of-DPLL-step′-DPLL-step*[*code abstract*]

lemma *Con-DPLL-step-rough-state-of-state-of*[*simp*]:
Con (*DPLL-step* (*rough-state-of s*)) = *state-of* (*DPLL-step* (*rough-state-of s*))
unfolding *Con-def* **by** (*metis* (*mono-tags*, *lifting*) *DPLL-step-dpll*$_W$*-conc-inv mem-Collect-eq prod.case-eq-if*)

A slightly different version of *DPLL-tot* where the returned boolean indicates the result.

definition *DPLL-tot-rep* **where**
DPLL-tot-rep S =
(*let* (*M*, *N*) = (*rough-state-of* (*DPLL-tot S*)) *in* (∀ *A* ∈ *set N*. (∃ *a*∈*set A*. *a* ∈ *lits-of-l* (*M*)), *M*))

One version of the generated SML code is here, but not included in the generated document. The only differences are:

- export *′a literal* from the SML Module *Clausal-Logic*;
- export the constructor *Con* from *DPLL-W-Implementation*;
- export the *int* constructor from *Arith*.

  All these allows to test on the code on some examples.

The condition of the differences of cardinality has to be strict. Otherwise, you could be in a strange state, where nothing remains to do, but a restart is done. See the proof of well-foundedness.

Luby sequences are defined by:

- $2^k - 1$, if $i = (2::'a)^k - (1::'a)$

- *luby-sequence-core* $(i - 2^{k - 1} + 1)$, if $(2::'a)^{k - 1} \leq i$ and $i \leq (2::'a)^{k} - (1::'a)$

Then the sequence is then scaled by a constant unit run (called *ur* here), strictly positive.

24 2-Watched-Literal

```
theory CDCL-Two-Watched-Literals
imports CDCL-WNOT
begin
```

We will directly on the two-watched literals datastructure with lists: it could be also seen as a state over some abstract clause representation we would later refine as lists. However, as we need a way to select element from a clause, working on lists is better.

24.1 Datastructure and Access Functions

Only the 2-watched literals have to be verified here: the backtrack level and the trail that appear in the state are not related to the 2-watched algoritm.

```
datatype 'v twl-clause =
  TWL-Clause (watched: 'v literal list) (unwatched: 'v literal list)

datatype 'v twl-state =
  TWL-State (raw-trail: ('v, nat, 'v twl-clause) marked-lit list)
```

```
    (raw-init-clss: 'v twl-clause list)
    (raw-learned-clss: 'v twl-clause list) (backtrack-lvl: nat)
    (raw-conflicting: 'v literal list option)

  by (induction l) auto
```

24.2 Invariants

We need the following property about updates: if there is a literal L with $-\ L$ in the trail, and L is not watched, then it stays unwatched; i.e., while updating with *rewatch* it does not get swap with a watched literal L' such that $-\ L'$ is in the trail.

```
primrec watched-decided-most-recently :: ('v, 'lvl, 'mark) marked-lit list ⇒
  'v twl-clause ⇒ bool
  where
watched-decided-most-recently M (TWL-Clause W UW) ⟷
  (∀ L'∈ set W. ∀ L∈ set UW.
    −L' ∈ lits-of-l M ⟶ −L ∈ lits-of-l M ⟶ L ∉# mset W ⟶
      index (map lit-of M) (−L') ≤ index (map lit-of M) (−L))
```

Here are the invariant strictly related to the 2-WL data structure.

```

```

26 Implementation for 2 Watched-Literals

```
theory CDCL-Two-Watched-Literals-Implementation
imports CDCL-Two-Watched-Literals-Invariant
begin
```

The general idea is the following:

1. Build a "propagate" queue and a conflict clause.
2. While updating the data-structure: if you find a conflicting clause, update the conflict clause. Otherwise prepend the propagated clause.
3. While updating, when looking for conflicts and propagation, work with respect to the trail of the state and the propagate queue (and not only the trail of the state).
4. As long as the propagate queue is not empty, dequeue the first element, push it on the trail (with the *conflict-driven-clause-learning*$_W$*.propagate* rule), propagate, and update the data-structure.
5. if a conflict has been found such that it is entailed by the trail only (i.e. without the propagate queue), then apply the *conflict-driven-clause-learning*$_W$*.conflict* rule.

It is important to remember that a conflicting clause with respect to the trail and the queue might not be the earliest conflicting clause, meaning that the proof of non-redundancy should not work anymore.

However, once a conflict has been found, we can stop adding literals to the queue: we just have to finish updating the data-structure (both to keep the invariant and find a potentially better conflict). A conflict is better when it involves less literals, i.e. less propagations are needed before finding the conflict.

```
datatype 'v candidate =
  Prop-Or-Conf
    (prop-queue: ('v literal × 'v twl-clause) list)
    (conflict: 'v twl-clause option)
```

Morally instead of (*'v literal* × *'v twl-clause*) *list*, we should use (*'v*, *nat*, *'v twl-clause*) *marked-lits* with only *Propagated*. However, we do not want to define the function for *Marked* too. The following function makes the conversion from the pair to the trail:

```
abbreviation get-trail-of-cand where
get-trail-of-cand C ≡ map (case-prod Propagated) (prop-queue C)

datatype 'v twl-state-cands =
  TWL-State-Cand (twl-state: 'v twl-state)
    (cand: 'v candidate)

fun find-earliest-conflict :: ('v, nat, 'v twl-clause) marked-lits ⇒
  'v twl-clause option ⇒ 'v twl-clause option ⇒ 'v twl-clause option where
find-earliest-conflict - None C = C |
find-earliest-conflict - C None = C |
find-earliest-conflict [] C - = C |
find-earliest-conflict (L # M) (Some C) (Some D) =
  (case (M ⊨a mset (raw-clause C), ¬M⊨a mset (raw-clause D)) of
    (True, True) ⇒ find-earliest-conflict M (Some C) (Some D)
  | (False, True) ⇒ Some D
  | (True, False) ⇒ Some C
  | - ⇒ Some C)

lemma find-earliest-conflict-cases:
  find-earliest-conflict M (Some C) (Some D) = Some C ∨
  find-earliest-conflict M (Some C) (Some D) = Some D
  by (induction M) (auto split: bool.splits)
```

While updating the clauses, there are several cases:

- L is not watched and there is nothing to do;
- there is a literal to be watched: there are swapped;
- there is no literal to be watched, the other literal is not assigned: the clause is a propagate or a conflict candidate;
- there is no literal to be watched, the other literal is $-\ L$: the clause is a tautology and nothing special is done;
- there is no literal to be watched, but the other literal is true: there is nothing to do;
- there is no literal to be watched, but the other literal is false: the clause is a conflict candidate.

  The function returns a couple composed of a list of clauses and a candidate.

```
